

INJECTOR OF COMPACT DESIGN FOR A COMMON RAIL INJECTION SYSTEM
FOR INTERNAL COMBUSTION ENGINES

~~Prior Art~~

8/1

The invention relates to an injector for a common rail
5 injection system for internal combustion engines, having a
valve control chamber, defined by the end face of a nozzle
needle, in which the fuel inlet takes place via an inlet
throttle and the fuel outlet takes place via an outflow
throttle, and there is a closing piston in the valve control
chamber.

8/27

To reduce the structural length of conventional
injectors, various efforts have been made, with the goal of
constructing injectors in which the nozzle needle discharges
directly into the valve control chamber, and no valve piston
is necessary. From European Patent 0 426 205, an injector is
known in which the nozzle needle discharges directly into the
valve control chamber. Located in the valve control chamber
are a control element and a closing piston. A disadvantage of
this design is that the closing piston and the control element
with an inlet throttle and outflow throttle are disposed in
20 line with one another, so that despite the omission of the
valve piston, the structural length of the injector is still
comparatively great. Furthermore, the closing forces at the
end of injection are relatively slight.

237

The object of the invention is to furnish an injector that is especially compact in structure and simple in design, and in which the closing forces at the end of injection are high.

5 According to the invention, this object is attained by an injector for a common rail injection system for internal combustion engines, having a valve control chamber, defined by the end face of a nozzle needle, in which the fuel inlet takes place via an inlet throttle and the fuel outlet takes place via an outflow throttle, and there is a closing piston, which has a greater diameter than the nozzle needle, in the valve control chamber.

10 This injector has the advantage that its structural length is especially short, since there is only one closing piston in the valve control chamber. Furthermore, in the injector of the invention the closing force at the end of injection is especially high, because the diameter of the closing piston is greater than the diameter of the nozzle needle. Finally, by reducing the number of components of the injector, a simple design of the injector has been achieved.

20 A variant of the injector of the invention provides that the closing piston is disposed between the inlet throttle and outflow throttle on one side and the nozzle needle on the other, so that the closing piston also takes on control tasks.

1
In another embodiment, it is provided that the closing piston has a first bore, extending between its end faces, so that the positive displacement work which the nozzle needle must perform upon opening of the injection nozzle counter to the pressure in the valve control chamber is slight.

In an advantageous feature of the invention, the closing piston has a throttle bore extending between its end faces, so that after the end of injection, the closing piston can be returned to its outset position at a defined speed.

In a supplement to the invention, a stroke stop is provided in the valve control chamber and limits the displaceability of the closing piston in the direction of the inlet throttle and the outflow throttle, so that the fuel can flow unhindered into and out of this portion of the valve control chamber.

In a further version, a closing spring is present, which is braced against the closing piston and the nozzle needle, so that after the end of injection the closing piston is moved into its outset position by the spring force.

20 In an advantageous feature, it is provided that the closing spring is disposed in the valve control chamber, so that a simple design is assured, and the spring force acts directly on the closing piston.

In a supplement to the invention, it is provided that the closing spring is braced against the end face of the nozzle needle, so that the nozzle needle is simple in design.

Another variant provides that the nozzle needle has a pin protruding in the direction of its longitudinal axis and past its end face, so that the portion of the valve control chamber defined by the closing piston and the end face of the nozzle needle does not fail to attain a minimum volume predetermined by the length of the pin. Because of the elasticity of the fuel, this minimum volume brings about a certain elasticity or "softness" of the injector in the valve control chamber and the walls of the valve control chamber.

In another variant of the invention, the first bore of the closing piston is closable by the pin, so that with the injection nozzle open, the pressure in the valve control chamber between the closing piston and the nozzle needle drops no more than necessary, and the leakage losses between the nozzle needle and the valve control chamber are reduced.

In a supplement to the invention, it is provided that the first bore of the closing piston has a sealing seat on the face end toward the nozzle needle, and the pin has a corresponding sealing cone, so that especially good sealing between the pin and the closing piston is achieved.

A variant provides that the inlet throttle and/or the outflow throttle is disposed in a housing of the injector, so that the dimensions of the injector are reduced still further.

Further advantages and advantageous features of the invention can be learned from the ensuing description, the drawing and the claims. One exemplary embodiment of the subject of the invention is shown in the drawing and described in further detail below. Shown are:

Fig. 1: a cross section through an injector according to the invention; and

Fig. 2: an enlarged detail X of Fig. 1.

In Fig. 1, an injector according to the invention is shown. Via a high-pressure connection stub 1, fuel 3 is carried via an inlet conduit 5 to an injection nozzle 7 and via an inlet throttle 9 into a valve control chamber 11. The valve control chamber 11 communicates with a fuel return 17 via an outflow throttle 13, which can be opened by a magnet valve 15. The fuel 3 is shown in Fig. 1 as a black area.

The valve control chamber 11 is defined by a nozzle needle 21. The nozzle needle 21 prevents the fuel 3, which is under pressure, from flowing into the combustion chamber, not shown, between injections. This is achieved by the provision that the nozzle needle 21 is pressed into a nozzle needle seat

22 and seals off the inlet conduit 5 from the combustion chamber, not shown.

The nozzle needle 21 has a cross-sectional change 23 from a larger diameter 25 to a smaller diameter 27. The nozzle needle 21 is guided with its larger diameter 25 in a housing 29. The cross-sectional change 23 defines a pressure chamber 31 of the injection nozzle 7.

July 1957
In Fig. 2, an enlarged detail X of Fig. 1 of the injector of the invention is shown. In this view it can be seen that the valve control chamber 11 is defined by an end face 33 of the nozzle needle 21. A closing piston 34 is located in the valve control chamber 11 and has a first, larger bore 35 and a second, smaller throttle bore 36. The stroke of the closing piston 34 in the direction of the magnet valve 15 is limited by a stroke stop 37. A pin 38 with a conical tip that fits into a complimentary sealing seat 39 of the closing piston 34 protrudes from the end face 33 of the nozzle needle 21. Fig. 2 shows a state of the injector in which the closing piston 34 rests on the stroke stop 37, and the nozzle needle is seated on its nozzle needle seat 22, not shown in Fig. 2. In this position, there is a gap between the pin 38 and the sealing seat 39 of the closing piston 34, so the fuel 3, not shown in Fig. 2, can flow through the first bore 35 of the closing piston 34 into the part of the valve control chamber 11 located between the closing piston 34 and the nozzle needle 22.

chamber 11. The opening speed of the nozzle needle 21 is determined by the difference in flow between the inlet throttle 9 and the outflow throttle 13.

This indirect triggering of the nozzle needle 21 via a hydraulic force booster system is necessary, because the forces required for rapid opening of the nozzle needle 21 cannot be generated directly with the magnet valve 15. The so-called "control quantity" required in addition to the fuel quantity injected into the combustion chamber reaches the fuel return 17 via the inlet throttle 9, the valve control chamber 11, and the outflow throttle 13. In addition to the control quantity, leakage also occurs at the nozzle needle guide. The control and leakage quantities can amount to up to 50 mm³ per stroke. They are returned to the fuel tank, not shown, via the magnet valve 15.

Ins 7
027 To terminate the injection, the outflow throttle 13 is closed by the ball 41 of the magnet valve 15, in a manner not explained in further detail. As a result of the closure of the outflow throttle 13, virtually the same rail pressure builds up again via the inlet throttle 9 in a portion 43 of the valve control chamber 11 that is defined by the closing piston 34 and the outflow throttle 13. This pressure exerts a hydraulic force on the nozzle needle 21 via the end face 45 of the closing piston 34 and via the pin 38 resting on the sealing seat 39. As soon as this hydraulic force exceeds the hydraulic force acting on the cross-sectional change 23, the

nozzle needle 21 closes. Because the end face 45 of the closing piston is markedly larger in comparison to the annular face of the cross-sectional change 23, the closing motion takes place very fast and with great force. Simultaneously with the closing motion, a small portion of the fuel, flowing into the portion 43 of the valve control chamber 11, flows through the throttle bore 36 into the valve control chamber 11 defined by the closing piston 34 and by the end face 33 of the nozzle needle 21. The closing motion takes place so fast that before a pressure equalization is reached, the nozzle needle 21 rests on the nozzle needle seat 22 again, and the injection is terminated. The closing speed of the nozzle needle 21 is determined essentially by the flow through the inlet throttle 9.

In order for the closing piston 34 to move to the outset position against the stroke stop 37 after the end of injection, the portion of the valve control chamber 11 defined by the closing piston 34 and the end face 33 of the nozzle needle 21 is filled with fuel through the throttle bore 36, while the closing spring 40 presses the closing piston 34 upward. It also conceivable to omit the throttle bore 36 and to dimension the play of the closing piston 34 in the housing 29 in such a way that the fuel flows through the annular gap between the closing piston 34 and the housing 29. The second end face 47 of the closing piston 34 can also, as shown in Fig. 2, have a shoulder, which serves for instance to guide the closing spring 40.
